APPENDIX D

DATA QUALITY SUMMARY

APPENDIX D

DATA QUALITY SUMMARY

Blank samples were collected and analyzed throughout the Moffett Federal Airfield (MFA) remedial investigation (RI). Blank samples are analyzed to determine the existence of contamination problems resulting from laboratory or field activities. Therefore, if a chemical is detected in a blank sample, detections in associated environmental samples may be a field or laboratory artifact. When this occurs, concentrations of the chemical detected in the environmental sample that are less than ten times (for common laboratory contaminants [CLCs]) or five times (all other chemicals) the concentration detected in the blank are qualified as not detected in the environmental sample (EPA 1994a and 1994b).

A database query was conducted to assess the presence of field and laboratory artifacts in samples collected during the PRC Environmental Management, Inc. and Montgomery Watson (PRC and MW) sampling programs. This query identified the frequency of chemicals detected in equipment rinsates, field blanks, trip blanks, and laboratory method blanks. The results of this query provide an indication of constituents that are field or laboratory artifacts. This query does not associate detections in blanks to specific samples or provide detected concentrations; therefore, the five and ten times rules were not applied. For all validated data, blank detections are reflected in sample result qualifiers.

This blank data review provided information to make general assessments of potential field or laboratory contamination. For the various types of blanks, some chemicals were infrequently detected. The infrequently detected chemicals were addressed during data validation and detections in blanks and associated samples were qualified appropriately. CLCs were detected frequently in blank results. CLCs detected in environmental samples should be thoroughly scrutinized to determine their source. Overall, field and laboratory artifacts in blank samples were frequently limited to CLCs.

Equipment Rinsates

Equipment rinsates are distilled and deionized organic free water rinses of sampling equipment collected after equipment decontamination was conducted. These samples indicate chemicals not removed from sampling equipment during decontamination that may result in cross contamination in subsequent samples. Also, equipment rinsates were collected from disposable equipment, such as disposable bailers, to determine the potential of this equipment as a source of field contamination. Equipment rinsates were analyzed for volatile organic compounds (VOCs), semivolatile organic

compounds (SVOCs), total petroleum hydrocarbons (TPHs), organophosphorus pesticides, polychlorinated biphenyls (PCBs), and total and dissolved metals. Results of equipment rinsate analyses are discussed below and their frequencies summarized in Tables D-1 through D-5.

The frequency of detection of VOCs and TPHs in equipment rinsates are presented in Table D-1. Most constituents were either not detected or detected infrequently. Those constituents detected infrequently are indicative of isolated occurrence of field or laboratory contamination. More frequently detected constituents in equipment rinsates (detected in more than 5 percent of the equipment rinsate samples) were 2-butanone, acetone, chloroform, methylene chloride, other light TPH components, toluene, trichloroethene (TCE), and xylene. Acetone, 2-butanone, and methylene chloride are CLCs. Chloroform is common in treated water and may be a remnant of decontamination rinse water. The other light TPH components, toluene, TCE, and xylene detections are likely residual contamination from collection of environmental samples. The greatest frequency of other light TPH components, toluene, and xylene detections were detected during TPH gasoline analysis. Toluene and xylene were less frequently detected in other analyses (for example, VOC analysis). TCE is a known soil and groundwater contaminant at MFA; the presence of TCE in equipment rinsates may be a result of its occurrence within sample media that was not removed from sampling equipment during decontamination. Since the data has been validated, any detections of TCE in associated equipment rinsates and environmental samples were qualified appropriately.

The frequency of SVOC detections are presented in Table D-2. Bis(2-ethylhexyl)phthalate, butylbenzylphthalate, di-n-butylphthalate, di-n-octylphthalate, diethylphthalate, and phenanthrene were all detected at least once in equipment rinsate samples. The phthalate compounds are CLCs. Phenanthrene was detected only once in 29 equipment rinsates. The phenanthrene detection is an isolated occurrence and should not affect the overall data.

Table D-3 presents the frequency of detections of pesticides and PCBs. Only 4,4'-DDE was detected. 4,4'-DDE was detected once in 21 equipment rinsates. This detection is isolated and should not impact the overall data.

The frequency of total and dissolved metals detections in equipment rinsates are presented in Tables D-4 and D-5. Most metals were detected during total and dissolved analysis. These detections are a result of residuals on sampling equipment after decontamination, a result of metal present in the sampling equipment, or a result of constituents in rinse water.

Field Blanks

Field blanks are samples collected of decontamination source water, drilling source water, or of deionized and distilled organic free water used for equipment rinsates. These blanks assess presence of chemicals in water used during drilling or sampling, or airborne contaminants that may impact environmental sample integrity. Field blanks were analyzed for VOCs, TPHs, SVOCs, organophosphorus pesticides, PCBs, and total and dissolved metals.

Table D-6 presents the frequency of detection of VOCs and TPHs. Acetone, 1,2-dichloroethene, benzene, bromoform, carbon disulfide, chloroform, dibromochloromethane, dichlorobromomethane, methylene chloride, other heavy and light TPH components, toluene, TCE, and xylene were all detected at least once in field blanks. Trihalomethanes (bromoform, chloroform, dibromochloromethane, and dichlorobromomethane) are common in treated water and can be expected in source water field blanks. Acetone and methylene chloride are CLCs; their detection in field blanks is probably a result of laboratory contamination. Detections of heavy and light TPH components occurred two and four times, respectively, in eight field blanks. The detections of these TPH components are unclear, but they may be present in source water. The other chemicals detected in field blanks were infrequent and probably a result of isolated field or laboratory contamination.

The presence of SVOCs in field blanks was isolated to phthalates and n-nitrosodiphenylamine. The phthalates are CLCs. N-nitrosodiphenylamine may be an analytical system residual (see discussion of n-nitrosodiphenylamine under method blanks). N-nitrosodiphenylamine detections should not affect the overall data. Table D-7 presents the frequency of detections of SVOCs in field blanks.

Heptachlor and 4,4'-DDT were the only PCBs or pesticides detected in field blanks. They were each detected only once in seven field blanks. These detections were isolated and should not impact the overall data. Table D-8 presents the frequency of detection of PCBs and pesticides.

Various metals were detected in the field blanks. These metals are probably present in low levels in source water and should not have a significant affect on the data. Tables D-9 and D-10 present the frequency of detection of metals in field blanks.

Method Blanks

A method blank consists of deionized and distilled water and reagents used in the analytical procedure. Method blanks are analyzed to determine presence of laboratory contamination during preparation and analysis of environmental samples. Individual methods prescribe the frequency of method blank analysis. This section discusses the results for VOC, TPH, SVOC, PCB, and organophosphorus pesticide analyses in method blanks.

Twenty-three different VOCs or TPH components were detected in the method blanks. Table D-11 presents the frequency of detection of VOCs and TPHs in method blanks. Most of these detections were infrequent and associated environmental samples were qualified appropriately for these isolated detections. Acetone and methylene chloride were detected frequently, but both chemicals are CLCs.

Table D-12 presents the frequency of detection of SVOCs in method blanks. Phthalates, fluoroanthene, n-nitrosodiphenylamine, and pyrene were all detected in method blanks. Phthalates are CLCs. The detections of fluoranthene and pyrene were infrequent and should impact overall data quality. N-nitrosodiphenylamine was detected in 24 of 108 method blanks. The source of n-nitrosodiphenylamine is unclear, but associated samples were qualified appropriately and this SVOC is not a contaminant at MFA. These detections are possibly related to residual contamination in the analytical system from samples run prior to the method blanks.

Table D-13 presents the frequency of detection of PCBs and organophosphorus pesticides. Heptachlor, methoxychlor, 4,4'-DDE, and 4,4'-DDT were all detected in method blanks. Methoxychlor, 4,4'-DDE, and 4,4'-DDT were all detected only once in 72 method blanks. Heptachlor was detected three times in 72 method blanks. The infrequent detection of these pesticides in method blanks should not impact the overall data. All associated samples were qualified appropriately.

Trip Blanks

Trip blanks are prepared in the lab with deionized and distilled organic free water and are placed in all sample coolers containing samples to be analyzed for VOCs and volatile TPH components. Trip blanks determine if environmental samples were contaminated during transit.

Twenty-eight VOCs or TPH components were detected in trip blanks. Most were infrequently detected and associated samples were qualified appropriately. Frequent detections of acetone and methylene chloride occurred and are probably laboratory artifacts. Table D-14 presents the frequency of detection of VOCs and TPH components in trip blanks.

APPENDIX D - DATA QUALITY SUMMARY

The following table identifies the data quality summary reports found in Appendix D. The table numbers have been generated using the following conventions, where the "D" represents the Appendix. The number following the "D" represents the sample matrix. The number following the first decimal point represents the analytical analysis and the number following the second decimal represents the quality assurance sample type. For example, a surface water duplicate sample analyzed for total metals can be located in table D3.4.1. An "X" indicates that a report is included in this Appendix.

Analysis #	Analysis	Sample Matrix 1 Soil				Sample Matrix 2 Sediment				Sample Matrix 3 Surface Water				Sample Matrix 4 Groundwater			
		QA Sample Number				QA Sample Number				QA Sample Number				QA Sample Number			
		FD 1	FB 2	ER 3	TB 4	FD 1	FB 2	ER 3	TB 4	FD 1	FB 2	ER 3	TB 4	FD 1	FB 2	ER 3	TB 4

21	MOLYBDENUM	X				X				X				X		X	

X = There is a report
 = Report not appropriate

FD = Field Duplicate
 FB = Field Blank
 ER = Equipment Rinsate
 TB = Trip Blank

Naming Convention:

D Matrix Number. Analysis Number. QA Sample Number

All field blanks, equipment rinsates, and trip blanks are included under the groundwater sample matrix since these samples are actually water samples. Therefore, the blank samples that relate to soil, sediment, and surface water samples can be found in the groundwater tables. To increase useability, the data quality summary tables are listed in chronological order. To compare sample results with blank sample results, use the "sample date."

The following indices list all the samples included in each table. The table numbers have been created using the above report conventions. The table numbers are not sequential since not all possible combinations are appropriate.
